A tranche is the atomic unit of credit in Lotus. It is defined by a loan asset, a collateral asset, a liquidation loan-to-value ratio (LLTV), and an oracle configuration.

Ticks chain together to form continuous markets. A continuous market is an ordered hierarchy of ticks that share a loan asset. The order follows a chosen risk axis, such as an ascending LLTV, an ascending time-to-maturity, or a descending collateral quality. The hierarchy governs liquidity routing, relative pricing, and the allocation of losses.

A risk curve maps borrowing rates to the risk axis. In a continuous market where ticks share the same collateral and vary only by LLTV, the curve is flat where LLTVs present an immaterial risk of bad debt. At these LLTVs, rates hover at a global base rate plus a liquidity premium. Past an inflection point, there is a material risk of bad debt, and so rates rise exponentially with increasing LLTV.
